Running headline: The popler database and R package

^{*}aldo.compagnoni@gmail.com

Abstract

- 1. Population dynamics play a central role in the historical and current development of fundamental and applied ecological science. The nascent culture of open data promises to increase the value of population dynamics studies to the field of ecology. However, the access and use of population data is constrained by the difficulty in identifying relevant datasets, by the heterogeneity of available data, and by access to raw (as opposed to aggregated or derived) observations.
- 2. To obviate these issues, we built a relational database, popler, and its R client, library("popler"). popler accommodates the vast majority of population data under a common structure, and without the need for aggregating raw observations. library("popler") is designed for users unfamiliar with the structure of the database and with the SQL language. This R library allows users to identify, download, explore, and cite datasets salient to their needs.
- 3. We implemented popler as a PostgreSQL instance, where we stored population data originated by the United Stated Long Term Ecological Research (LTER) Network. Our focus on the US LTER data aims to leverage the untapped potential of this vast open data resource. The database currently contains 305 datasets from 25 LTER sites. popler is designed to accommodate automatic updates of existing datasets, and to accommodate additional datasets from LTER as well as non-LTER studies.
- 4. The combination of the online database and the R library("popler") is a unique data resource in population ecology. The common structure of popler simplifies comparative analyses, and the availability of raw data confers flexibility in data analysis. library("popler") maximizes these opportunities by providing a user-friendly interface to the online database.

Keywords

3 Introduction

29

Population dynamics – changes in species' abundance and composition through time and space - are central to ecology for both applied and fundamental reasons. Populations are the building blocks of ecological dynamics at higher scales of organization, and examples abound showing how the study of population ecology improves understanding in evolution (?), community ecology (?), and ecosystem ecology (??). Given their central role, studies of population dynamics will be an essential component in the advances allowed by the flourishing culture of open access. The increase in freely available data is poised to change ecological science (?). The rising 10 focus on open data is clear in changing publishing standards, in the design of observational 11 networks (?), and in the availability of previously proprietary data (??). This deluge of open 12 data holds promise to facilitate comparative analyses and to test the generality of ecological hypotheses. For population dynamics in particular, it is the increasing availability of long-term 14 data that will likely yield the most substantial scientific advances, as long time series are required to detect trends in abundance (?), quantify temporal variance (?), and identify endogenous (?) or exogenous (?) drivers of population fluctuations. There are currently three public databases that provide time series of population data. These are the Global Population Dynamics Database (GPDD, ?), the Living Planet Index (?), and 19 BioTIME (?). These databases are an important resource for population biologists (e.g., ?), but 20 their characteristics make them optimal for a specific set of analyses. For example, the GPDD 21 time series contain only one observation of population size or density per temporal replicate, 22 BioTIME focuses on assemblage (i.e. multispecies) datasets, and the Living Planet Index contains 23 information on single populations of conservation concern. These differences can be decisive in scientific inference. For example, LPI data indicate worldwide biodiversity declines, while 25 BioTIME data indicate stable biodiversity due to higher species turnover. This is likely due to the focus of the LPI on species of conservation concern (?). Finally, none of these three databases 27 provides much data from experiments. One of the best sources of publicly available long-term data is the Long-Term Ecological

Research (LTER) network. The LTER was founded in 1980 and grew from the original six sites to, as of 2016, 28 sites throughout North America, Puerto Rico, French Polynesia, and Antarctica.

Synthetic and comparative studies from the LTER network have made valuable contributions to ecological understanding (?). However, the majority of LTER synthesis research has focused on ecological dynamics at the community (e.g. ?) and ecosystem (e.g. ?) scales. Nevertheless, every LTER site collects population abundance data as one of its five core areas of continuous observations (?). In our opinion these data, which have been accumulating since 1980, are under-used.

LTER population data provides two distinct advantages compared to existing databases.

First, LTER data contains both single-species and assemblage datasets that might be free from
the biases suggested for the LPI database. Assemblage datasets are expected to be an unbiased
reflection of biodiversity trends (?), and LTER single-species studies are generally not focused
on species of conservation concern. Second, many of the analyses on LTER experiments were
published a few years after the start of manipulations. Hence, analysis of updated data from
these LTER experiments could provide unique scientific insights.

One issue that may limit the use of LTER population data is their heterogeneity. The structure of LTER data sets may be widely different, employing a variety of data types (counts of individuals, biomass estimates, percent cover, etc.), experimental designs driven by the priorities of particular PIs, and diverse replication schemes – idiosyncrasies that may be difficult to accommodate in a one-size-fits-all database. However, these challenges also present valuable opportunities. For example, the hierarchical replication structure of many LTER studies (e.g., subplots within plots within transects) can facilitate more sophisticated statistical investigation than would be possible with simpler, aggregated, or unreplicated data.

To overcome the issues posed by heterogeneous data structures, we developed popler (POPulation dynamics in Long-term Ecological Research), an online database of LTER population
studies. This database defines a common data structure that can accommodate in principle all
population data, and its SQL environment allows updates whenever new data becomes available.
We also developed a companion R package to facilitate the identification, access, and manipulation of raw and heterogeneous population data. Our goals here are to provide introductions to
the database and package. We focus on LTER time series, but expanding popler beyond the
LTER network is a priority for future development.

61 The popler database

- To combine population data from the LTER network using a common structure, we identified
 a set of relevant variables (Table ??) and organized them into a relational database. Here, we
 present the structure of the database in Fig. ??, and we provide a simplified entity relationship
 diagram (ERD) in the supplementary material (Fig. ??). In popular we stored "raw" data,
 meaning that we have not modified, edited, or aggregated the original observations.

 For inclusion in popular, we only considered studies that included (1) repeated observations
 of populations or individuals through time, (2) at least five population censuses (as of database
 creation in 2017), and (3) taxonomic information associated with abundance observations (e.g.,
 we excluded time series of functional groups). We provide technical details of database creation
 in Appendix S1.
- The popler database currently contains data from 305 studies (122 of which are experimental) representing 4377 cumulative years of observations. On average, studies in popler contain 10.5 years of data (median: 7), with the longest study containing 67. The sampling designs are predominantly yearly (49%) and sub-yearly (44%), and only 6% of designs sampled populations irregularly or less often than yearly. popler also contains abundant spatial replication, with studies containing a mean of 295 (median: 72) unique spatial replicates distributed across an average of 2.4 (median: 2) nested spatial replication levels. Finally, popler contains data from 665 plant species, 382 animal species, and 1 fungal species.

■ Population data

- We define "population data" as time-series of observations on the size or density of a population
- 82 of a species or other taxonomic unit. Observations of population size are stored in a variable
- sa called abundance_observation and can be measured as a count, biomass, density, or cover.
- These four types of population data are stored in the homonymous tables of the database (Fig.
- 85 ??A).
- The population datasets contained in popler are always replicated temporally. Temporal
- 87 replicates are identified with up to three variables: year, month, and day. Population data are
- also almost always spatially replicated, and spatial replicates are often nested, where for example

a study might include separate sites, each of which contains intermediate spatial replicates (e.g. a transect, a block), which in turn contain the smallest spatial replicate at which observations are made (e.g. a plot, a quadrat). The hypothetical study described above would have three nested levels of spatial replication, identified by three numbered spatial_replication variables. In popler, we accommodate data sets with up to five spatial replication levels (Table ??). We call the first and therefore largest spatial replicate "study site" (Fig. ??C). Note that this does not refer to the LTER site, one of the 28 NSF-supported locations (Table ??).

popler contains both observational and experimental studies. Experimental datasets contain information on one or more experimental treatments. Popler accommodates information on up to three experimental treatments, identified by three numbered treatment_type variables (Table ??).

1 01

1 02

1 03

1 04

1 05

1 06

107

Most datasets also contain one or more variables in addition to the ones described above which we store in a character variable called covariates (Table ??). These are variables that do not conform to our data model. covariates stores in each row, the content an arbitrary number of such non-conforming variables. covariates can be useful, for example, for time series that contain information on population structure. In these datasets, observations on population size are grouped based on subdivisions of the entire population, such as males and females, large and small individuals, etc. We identify these datasets through a variable in the metadata structured_data (Table ??).

Finally, in addition to time series of abundance, popler contains individual-level data. This 1 08 data provides information on the attributes of the individuals, or a subset thereof, that make up a population. We store this information in a dedicated table ("Individual", Fig. ??A). As 110 individual attributes we consider variables that describe identity, size, sex, life stage or status 111 (e.g. reproductive or non-reproductive). We refer to these individual attributes with the term 112 "structure": popler accommodates data sets that measure up to four types of structure simul-113 taneously. We store these data in up to four numbered structure_type variables. While 114 these data are not population time series; we chose to include them in popler because they 115 provide information on demographic transitions that can be used to derive estimates of popula-116 tion growth. Moreover, in the cases of datasets that sample all of the individuals in a population, 117 individuals can be aggregated (i.e. summed) as a measure of population size.

19 Taxonomic information

Each observation corresponds to a taxonomic unit (Fig. ??B), typically a species or a genus, but 120 also include data that refer to a higher taxonomic rank, such as family, or order. popler provides 121 15 taxonomic ranks, and two additional variables that refer to how taxonomic information is 122 recorded in the original datasets. The additional variables are sppcode, which are taxon-specific 123 alphanumeric codes, and common_name, the common name of each taxonomic unit (Table S1). 1 24 popler also allows to store accepted taxonomic information in an additional table (Fig. ??B). 1 2 5 This table accounts for ambiguities contained in the raw taxonomic data, which originate by the dynamic changes in species classifications (?). Further versions of popler will populate this 127 second table with the accepted taxonomic units (which include taxonomic information above the level of genus) provided by the R package taxize (?). 129

130 Study site

We stored the locations of datasets by recording the latitude (lat_study_site) and longitude (lng_study_site) of study sites (Fig. ??C). Storing this information in a separate table allows for explicit connections between independent data sets collected at the same locations within LTER sites.

135 Metadata

The metadata table (Table ??) provides information on temporal and spatial replication, and 1 36 study design (Fig. ??D), including title, link to online metadata, contact information for data originators, and the type of data provided by the dataset (i.e., which of the five tables in Fig. ??A the data is stored in). All remaining metadata is related to the variables stored 1 39 in the tables of ??A and ??B. First, some population datasets subdivide the population in 140 groups that share the same characteristic (e.g. sex, developmental stage, age). These datasets, 141 however, are not individual data (Fig. ??D). We flag these datasets through the variable 142 structured_data. Second, we provide the years elapsed between the first and last obser-143 vation (duration_years), and the sampling frequency (samplefreq). Third, we provide the number of levels of nested spatial replicates, and the number of replicates for each spatially nested level. Fourth, we show whether studies focus on a single species or on multiple species through the community variable. Fifth, we identify studies as observational or experimental (studytype). If a study is experimental, we provide information on the type of treatments imposed by the study (treatment_type_n) and, when available, which one is the control treatment (control_group). Finally, we report information on the data stored in the abundance_observation variable: its units of measure (samplingunits), the area over which this abundance data was observed (spatial_replication_level_n_extent and spatial_replication_level_n_extent_units), and in case the data was aggregated across space or time we flag these data as derived (derived).

The popler package

The popler R package consists of three core functions that allow users to browse and retrieve data from the database (Fig. ??). In order of intended use, these functions are: pplr_dictionary(), pplr_browse(), and pplr_getdata().

159 The pplr_dictionary() function

The dictionary function is a good place for new users to begin working with popler (Fig. ??).

With no arguments provided, this function returns a subset of the most useful metadata variables
associated with each dataset (Fig. ??). Providing argument full_tbl = TRUE returns all
results as a subset of the most useful metadata variables
associated with each dataset (Fig. ??). Providing argument full_tbl = TRUE returns all
results as a summer to pplr_dictionary(), which then returns the possible unique values of the variable. For
example, pplr_dictionary(lterid) returns the three letter codes of the LTER network sites
included in popler. For numeric variables such as duration_years, pplr_dictionary()
returns a summary including quantiles, mean, and median.

168 The pplr_browse() function

Once the user is familiar with the meaning and content of the variables that define popler datasets, they are ready to dig deeper using pplr_browse() (Fig. ??). Running pplr_browse() without arguments provides the metadata from the entire contents of the database. This will be

a 305by20 data frame, with each row corresponding to a study and each column corresponding to a variable defined by pplr_dictionary().

The full strength of pplr_browse() is achieved by subsetting studies according to desired criteria using logical expressions. For example, the user might want to consider only studies whose duration is 30 years or greater, which can be subsetted with:

```
LTER_30 <- pplr_browse ( duration_years > 29)
```

This operation will create the object LTER_30, which provides metadata for the data sets
that satisfy the specified criterion. Multiple criteria may be combined. For example, 30+ year
studies of plants can be browsed with

To facilitate data exploration, pplr_browse() output can be printed in a more readable settings by providing report = TRUE as an argument, which opens up a formatted html document. The metadata provided by pplr_browse() not only contains information on the characteristics of a study but also information on how to cite the study, its unique identifiers, including digital object identifier (DOI), and the contact information of study PIs.

185 The pplr_get_data() function

Once data sets of interest have been identified, pplr_get_data() downloads the data from a server that hosts the database. This function can take as its first argument a browse object, a logical expression, or both. The data downloaded from popler are in "long" form, meaning that each row of data reports a single measure of population size, and separate variables indicate the temporal and spatial replicate, taxa, etc. This format makes it easy to further subset downloaded datasets with the aim of visualization and analysis.

192 Ancillary functions

popler also provides three additional functions to open the url of the original dataset, unpack covariates, and provide a citation for each dataset. First, the function metadata_url() launches the online study description in a web browser. Second, the cov_unpack() function transforms the covariates variable into a data frame (which pplr_get_data() does not provide by default). Third, pplr_citation() generates a citation for the originators or each data set.

Limitations and opportunities for development

Working with raw, spatially replicated, and non-aggregated data provides key advantages in quantitative analyses of population dynamics which were a driving force behind the development of popler. However, users need to examine individual datasets and the associated online study descriptions to understand their peculiarities. Single datasets have unique idiosyncrasies that 203 require vetting. For example, many datasets have gaps or changes in the sampling design during 2 04 the length of the study, or the covariates variable can hold key information. Hence, we urge 205 authors to consult the online documentation of the original datasets. 206 In the future, there are opportunities to increase the size of popler and expand its scope. 207 First, because many of the studies included in popler are ongoing, there will be opportunities to 208 run regular updates aimed at including new observations in popler. Second, because our schema 209 (Fig. ??) is very general, the database could be expanded to include population datasets outside of the LTER network. Third, it would be valuable to explicitly associate popler's populationlevel data with environmental drivers, especially climate. Thus, it is our intention and hope that 212 the resources provided by popler will advance ecological understanding of population dynamics

- contributed to manuscript drafts and gave final approval for publication.

227 Data Availability

The popler R package is publicly available at https://github.com/ropensci/popler.

Table 1: Variables used to store population or individual data in popler.

Variable	Description
	<u> </u>
abundance_observation	Measure of population abundance at a specific time
	and location. This variable measures abundance as
	a count, biomass, density, or cover. For individual
	data sets this variable is always equal to 1, because
	each attribute or set of attributes refer to a single
	individual.
day	Day of observation
month	Month of observation
year	Year of observation
spatial_replicate_n	The n^{th} level of spatial replication, where
	spatial_replicate_1 is the study site. popler
	accommodates up to five levels of spatial replication.
treatment_type_n	For datasets originating from an experimental study,
_ 11 _	the n^{th} treatment. popler popler accommodates
	up to three treatments.
covariates	Ancillary observations that do not fall into the stan-
	dard schema of popler.
structure_type_n	For individual data, these variables measure the n^{th}
11	attribute of individuals (identity, size, sex, status,
	stage). popler accommodates up to four structure
	types per dataset.
	- J F F

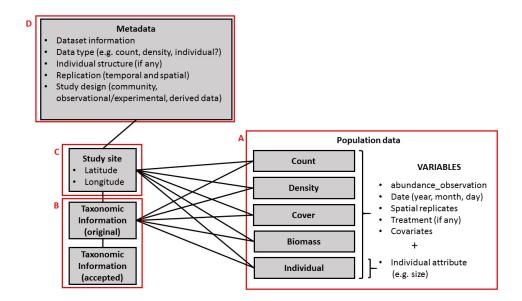

Figure 1: Schematic representation of the entity relationship diagram of the popler database. popler provides metadata on the studies that originated abundance data points (D). This metadata contains information on the unique identifiers of each study, on its design (observational or experimental), temporal and spatial replication. popler stores the latitude and longitude of the study site (C). Each abundance data point corresponds to a specific taxonomic unit (B). Finally, the time series of population data collected in a study can be of four different types (count, density, biomass, cover), or they may be individual data with attributes such as size or sex (A).

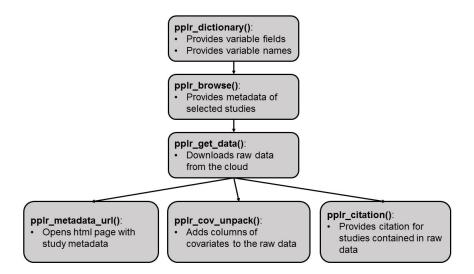

Figure 2: Suggested workflow when using the popler R package to interface with the homonymous online database. The function pplr_dictionary() refers to the variables of the metadata that describe the data sets contained in popler. pplr_dictionary() describes these variables and returns their possible values. This information advises which criteria to use when subsetting popler. The user can provide a criterion (that is, a logical statement) to browse the metadata, using pplr_browse(), or to download data using pplr_get_data(). Moreover, the output of pplr_get_data() (a data frame) can be the argument of three ancillary functions: pplr_metadata_url() opens the webpage containing the original dataset and their associated online metadata. pplr_cov_unpack() can be used to format the covariates contained in a raw data object into separate columns of a data frame. Finally, pplr_citation() provides a citation for the downloaded data set(s).

Appendix S1: Pre-processing popler data

Before uploading datasets into the online popler database, we combined datasets, transformed datasets from wide to long form, converted non-ASCII characters, and modified ambiguous study site names.

The variables of many datasets were contained in two or more separate files, which we com-233 bined in a single file. When the original dataset provided data in wide form, we transformed it into long form. In wide form datasets, abundance data associated with different species was stored in separate columns. popler stores these datasets in long form, whereby each row of 236 abundance data is related to a specific taxonomic unit in the table containing taxonomic infor-237 mation (Fig. ??B). We converted all data in ASCII format, because the encoding of the database 238 is the UTF-8. We often re-defined study site names to unambiguously associate them with one 239 of the 26 LTER sites. Many site names are alphanumeric codes (e.g. "U1") which can overlap 240 across several LTER sites. Hence, we changed site names following a standard formula (namely, from "U1" to "site_sbc_U1", where "sbc" refers to the Santa Barbara coastal LTER site). 242

In a handful of cases, we removed single data rows from the original dataset. These data rows were associated with two types of typos in the original dataset. First, some abundance observations were not associated with a time of observation. We removed this data because popler can only accommodate population information associated with a time of observation. Second, a handful of abundance data points were clear typos (e.g. the letter "l" instead of a numeric value). We substituted these data points with a missing value. We uploaded these pre-processed datasets in the popler database through a Graphic User Interface developed in Python using libraries panda and pyqt5.

Table S1: Taxonomic variables contained in the popler table on original taxonomic information.

Table S2: Metadata variables used to describe the datasets stored in popler.

Variable	Description
proj_metadat_key	Unique ID
lter_project_key	ID of LTER site
lter_project_key	ID of LTER site
title	Title of study
samplingunits	Unit of measure (if any) referred
	to population data.
datatype	Data type: count, biomass,
	cover, density, and individual.
	These correspond to the tables in
	Fig. 1A.
structured_data	If data type is not individual, but
	the abundance observations refer
	to sub-groups of the population
	based on, for example, sex, de-
	velopmental stage, or age)
structured_type_n	If individual data, this shows
	what type of structure is stored.
	A study can contain up to $n=4$
	types of structure.
structured_type_n_units	Unit of measure (if any) referred
	to structure data.
studystartyr	Start year of the study
studyendyr	End year of the study
duration_years	Duration of the study in years
samplefreq	Frequency of population census

studytype	Whether study is observational
	or experimental
community	Whether study includes sin-
	gle taxon (community = F) or
	multiple taxa (community =
	T)
spatial_replication_level_n_extent	Extent of spatial replication level
	number n . A dataset can have up
	to to 5 replication levels.
spatial_replication_level_n_extent_units	Unit of spatial extent of the n
	spatial replication level.
spatial_replication_level_n_label	Label of the spatial replica-
	tion level (e.g. transect, plot,
	quadrat, ect.). The label of spa-
	tial replication level 1 is "site".
spatial_replication_level_n_number_of_unique_reps	The number of unique replicates
	for the n th level of spatial repli-
	cation.
treatment_type_n	The type of treatment (e.g. re-
	source manipulation). A study
	can contain up to $n = 3$ treat-
	ments.
control_group	If study is experimental, this
	shows the field(s) that identify
	the control replicate.
derived	Is population size data raw, or is
	it derived (e.g. it is aggregated)?
authors	Author(s) of the original dataset

authors_contact	Email address(es) of the au-
	thor(s) associated with the orig-
	inal dataset.
metalink	url of the original dataset
knbid	Knowledge Network for Biocom-
	plexity identifier.

Table S3: LTER identification acronyms and their meaning as used in the popler database.
